

Class and object

Instance creator means object creation the represents allotting memory necessary to store the actual data of the variables.

#How to create object

Class Mobile:

```
def __init__(self,m):
    self.model = m

def show_model(self):
    print('Model',self.model)
```

```
realme = Mobile('RealMeX')
```

A block of memory is allocated on heap. The size of allocated memory is decided from the attributes and methods available in the class. After allocating memory block, the special method `__init__()` is called internally. This method stores the initial data in the variables. The memory which is already allocated in heap, its memory address will return in object realm.

The memory location is passed to self variable.

The self which stores the memory address of the current object because to current object, the memory location is returning.

Self variable which points to current object.
